## Conversions between Number systems

### Binary to Octal

- \* Group 3 binary bits each, starting from the right.

### Binary to Hexadecimal

- \* Group 4 binary bits each, starting from the right.

Eg - 101010011101<sub>2</sub>

$$\begin{array}{r} 1 \ 0 \ 1 \ 0 \quad 1 \ 0 \ 0 \ 1 \quad 1 \ 1 \ 0 \ 1_2 \\ \downarrow \qquad \downarrow \qquad \downarrow \\ A \qquad 9 \qquad D \ 16 \end{array}$$

### ★ Number Representation

#### → Sign Magnitude

### → One's Complement

\* positive numbers are represented in standard binary form.  
\* negative numbers are formed by flipping all bits- changing zeros to ones and ones to zeros.

Eg : -50 in One's complement

0 0 1 1 0 0 1 0	Original Binary Value
1 1 0 0 1 1 0 1	1's Complement

### → Two's Complement

\* positive numbers are represented in standard binary form.  
\* to obtain the negative value of a number, invert all the bits of its positive value and then add one to the result.

Eg : -65

0 1 0 0 0 0 0 1	Original Binary Value
1 0 1 1 1 1 1 0	1's Complement
+ 1	
1 0 1 1 1 1 1 0	2's Complement

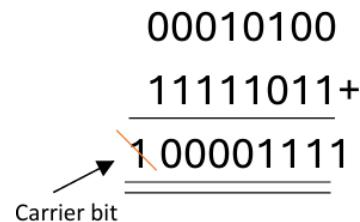

### Addition using 1's complement and 2's complement

- Computation  $20 + (-5)$  is done in 8-bit two's complement form.

$$20 \rightarrow 00010100$$

$$5 \rightarrow 00000101$$

$$-5 \rightarrow 11111010 + 00000001 = 11111011$$

\* In one's Complement additions, carrier bit is added again to the answer, But in Two's complement, carrier bit is ignored

## → Differences between 1's Complement and 2's Complement

1's Complement	2's Complement
1. Zero has two representations, +0 and -0	Zero has only one representation
2. Negative values obtained by flipping bits	To obtain a negative value, should flip bits and add 1
3. More complex for arithmetic operations due to considering carrier bit	Much easier in arithmetic operations
4. Less used in modern computing systems	Widely used in modern computer systems

## → Fixed point numbers

Eg :- 850.753

\* The decimal point is unchanged.

$$\begin{array}{r} 652.365 \\ + \\ 1503.118 \\ \hline \end{array}$$

## → Floating point numbers

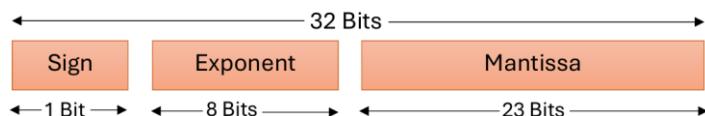

Used to represent:

- Numbers with fractions, such as 3.1416
- Very small numbers, like 0.000000001
- Very large numbers, for example,  $3.15576 \times 10^9$

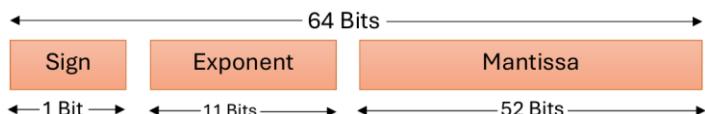

IEEE 754 standard has three main components:

1. Sign Bit: This indicates the sign of the number.
2. Exponent: A bias is added to the actual exponent
3. The Normalized Mantissa

### 1. Single Precision

### 2. Double Precision

## Advantages and disadvantages of Fixed-point and Floating-point representations

	Advantage	Disadvantage
Fixed Point Representation	The performance is good, not requiring extra hardware or software logic	Limited range of values can represent
Floating point representation	A wider range of numbers can be represented, with different levels of precision.	Requires more storage space, slower processing times, and reduced precision.

## → Coding systems used in Computers

### → Binary Coded Decimal (BCD)

- \* each decimal digit is represented by 4 bits.

Decimal value	BCD value
0	0000
1	0001
2	0010
3	0011
4	0100
5	0101
6	0110
7	0111
8	1000
9	1001

### → ASCII – American Standard Code for Information Interchange

- \* 7-bit code used to represent text in computers and communication devices.
- \* primary encoding system used in IBM PCs.

Extended ASCII expands this by using 8 bits

Eg:	Character	ASCII code	Binary code
	null	o	0000000
	a	97	1100001
	b	98	1100010
	0	48	0110000

### → EBCDIC (Extended Binary Coded Decimal Interchange Code)

- \* 8-bit character encoding is primarily used on IBM mainframe and midrange systems.

## Differences between ASCII and EBCDIC

ASCII	EBCDIC
Used for electronic communication	Used on IBM mainframe & IBM midrange computers
Uses 7 bits	Uses 8 bits
Only 128 characters can be represented	256 characters can be represented
Compatible with Unicode	Not compatible with Unicode
More efficient	Less efficient

## →UNICODE

- \* Widely adopted by major companies like Apple, HP, IBM, Microsoft, Oracle, SAP, and many others.
- \* It can store a vast number of characters, including those from almost every language in the world.

There are different types of Unicode:

- UTF-8: Uses 1 byte (8 bits).
- UTF-16: Uses 2 bytes (16 bits).
- UTF-32: Uses 4 bytes (32 bits).

## Differences between ASCII and Unicode

Property	ASCII	Unicode
<b>Space Requirement</b>	Needs less space	Needs more space than ASCII
<b>Bit Usage</b>	Uses 7 bits	Uses 8/16 or 32 bits
